Strings

Victor Eijkhout, Harika Gurram, Je'aime Powell, Charley Dey

Fall 2018

Characters

Characters and ints

- Type char;
- represents '7-bit ASCII': printable and (some) unprintable characters.
- Single quotes: char c = 'a'
- Equivalent to (short) integer: 'x'-'a' is distance a--x

Exercise 1

Code: Output:

```
int user_number;
                                                   echo 51 | ./digits
string user text{""}:
                                                  10<zero-nine>
vector<string> names{ "zero", "one", "two", "three",
                                                   Give a number:
    "four", "five", "six", "seven", "eight", "nine"};
                                                   Digit 0 from the end: 1=one
cout << names.size() << "<"
     << names[0] << "-" << names[9] << ">" << endl
Pigit 1 from the end: 5=five
                                                   That number in digits: fiveone
                                                   echo 2136 | ./digits
cout << "Give a number: ";
                                                   10<zero-nine>
cin >> user number: cout << endl:
                                                   Give a number:
                                                  Digit 0 from the end: 6=six
for (int d=0; user_number>0; d++) {
                                                  Digit 1 from the end: 3=three
  int remember = user number.digit:
                                                  Digit 2 from the end: 1=one
 user number = user number/10:
                                                  Digit 3 from the end: 2=two
 digit = remember-10*user_number;
                                                  That number in digits: twoonethreesix
 string name = names[digit]:
 cout << "Digit " << d << " from the end: " << digit << "=" << name << endl:
 user_text = name + user_text;
cout << "That number in digits: " << user text << endl:
```

Strings

String declaration

```
#include <string>
using std::string;
// .. and now you can use 'string'
```

(Do not use the C legacy mechanisms.)

String creation

A *string* variable contains a string of characters.

```
string txt;
```

You can initialize the string variable (use -std=c++11), or assign it dynamically:

```
string txt{"this is text"};
string moretxt("this is also text");
txt = "and now it is another text";
```

Concatenation

Strings can be concatenated:

```
txt = txt1+txt2;
txt += txt3;
```

String is like vector

You can query the size:

```
int txtlen = txt.size();
```

or use subscripts:

More vector methods

Other methods for the vector class apply: insert, empty, erase, push_back, et cetera.

Exercise 2

Code: Output:

```
int user_number;
                                                   echo 51 | ./digits
string user text{""}:
                                                  10<zero-nine>
vector<string> names{ "zero", "one", "two", "three",
                                                   Give a number:
    "four", "five", "six", "seven", "eight", "nine"};
                                                   Digit 0 from the end: 1=one
cout << names.size() << "<"
     << names[0] << "-" << names[9] << ">" << endl
Pigit 1 from the end: 5=five
                                                   That number in digits: fiveone
                                                   echo 2136 | ./digits
cout << "Give a number: ";
                                                   10<zero-nine>
cin >> user number: cout << endl:
                                                   Give a number:
                                                  Digit 0 from the end: 6=six
for (int d=0; user_number>0; d++) {
                                                  Digit 1 from the end: 3=three
  int remember = user number.digit:
                                                  Digit 2 from the end: 1=one
 user number = user number/10:
                                                  Digit 3 from the end: 2=two
 digit = remember-10*user_number;
                                                  That number in digits: twoonethreesix
 string name = names[digit]:
 cout << "Digit " << d << " from the end: " << digit << "=" << name << endl:
 user_text = name + user_text;
cout << "That number in digits: " << user text << endl:
```

Exercise 3

Write a function to convert an integer to a string: the input 205 should give two hundred fifteen, et cetera.
